### Solving SAT by swpSolver

- Basic scheme
- Our improvements

### **Our Parallel SAT-solver**

- The pure portfolio approach
- Failures
- Initialization with a guide of formula partitioning

#### Conclusion

## **Propositional Satisfiability Problem**

### **Notations**

- propositional variable: variable with two possible logical values true or false
- literal: an atomic formula either be a positive literal v or a negative literal  $\bar{v}$ .
- clause: disjunction of literals.
- CNF-formula: conjunction of clauses
- **assignment:**  $V \rightarrow \{ \textit{true}, \textit{false} \}$
- SAT problem: to determine whether a given formula is satisfiable or not

# Here is an example of SAT problem:

$$F = (v_1 \lor \bar{v_3}) \land (v_2 \lor v_1 \lor \bar{v_1})$$

$$Vars(F) = \{v_1, v_2, v_3\}$$

$$numV(F) = |Vars(F)| = 3$$

$$Lits(F) = \{v_1, \bar{v_1}, v_2, v_3, \bar{v_3}\}$$

$$Cls(F) = \{C_1, C_2\}$$

$$numC(F) = |Cls| = 2$$

$$C_1 = \{v_1, \bar{v_3}\}$$

$$C_2 = \{v_2, v_3, \bar{v_1}\}$$

 $A(v_1)$  = true,  $A(v_2)$  = false,  $A(v_3)$  = true, A is an assignment satisfying F.

 $\hat{A}(v_1) = true$ ,  $\hat{A}(v_2) = false$ ,  $\hat{A}(v_3) = false$ ,  $\hat{A}$  is an assignment with conflict in  $C_2$ .

## Local search in SAT problem

### **Local Search**

- an instance I of a hard combinational problem P
- a set of solutions S(I)
- an object function (score or cost) Γ
- to find the solution with minimum cost by applying local changes.

### Algorithmus 1 : Focused Local Search

input : A CNF Formula F

parameter : Timeout

output : a satisfying assignment A1 A ← random generated assignment A

- **2 while**  $(\exists$  *unsatisfied clause*  $\land$  *Timeout does not occur)* **do**
- $c \leftarrow \text{random selected unsatisfied clause}$
- $4 \quad x \leftarrow pickVar(A, c)$
- $5 \mid A \leftarrow flip(A, x)$

## Local search in SAT problem

### **Stochastic Local Search (SLS)**

- use the probability distribution of the scores of candidate solutions
- the more advantageous a move is, the higher is the probability of choosing that move

### Algorithmus 2: PickVar in probSAT

**input**: current assignment *A*, unsatisfied clause *c* 

**output** : a variable *x* in *c* to be flipped

- 1 **for** *v in c* **do**
- 2 | Evaluate v with function  $\Gamma(A, v)$ ;
- 3  $x \leftarrow$  randomly selected variable v in c with probability

$$p(v) = \frac{\Gamma(A, v)}{\sum_{u \in c} \Gamma(A, u)}$$

## Local search in SAT problem

### Random walk in local search

- originally introduced in 1994
- By introducing "uphill noises", the walkSAT combines greedy local search and random walk.

### Algorithmus 3: PickVar in walkSAT

**input**: current assignment *A*, unsatisfied clause *c* 

**parameter**: probability p

**output**: a variable x in c to be flipped

- 1 **for** *v in c* **do**
- 2 Evaluate v with function  $\Gamma(A, v)$ ;
- 3 with probability  $p: x \leftarrow v$  with maximum  $\Gamma(A, v)$ ;
- 4 with probability 1 p:  $x \leftarrow$  randomly selected v in c.

## **Outline**

# Solving SAT by swpSolver

**Basic scheme** 

### **Algorithmus 4:** Our Local Search

: A CNF Formula F input

parameter: Timeout

**output**: a satisfying assignment A

- 1  $A \leftarrow initAssign(F)$ ;
- 2 while (∃ unsatisfied clause ∧ Timeout does not occur) do
- $c \leftarrow pickCla(A)$ :
- $x \leftarrow pickVar(A, c)$ :
- $A \leftarrow flip(A, x);$

- 180 instances (UNIF) in random benchmark categories in SAT competition 2017
- All the clause have the same length k in a UNIF problem file.
- to construct one clause, k literals are randomly chosen from the 2n possible literals
- At least 60 (33%) problems form our 180 benchmark collections are unsatisfiable.
- Each experiment is repeated three times.
- PAR-2 runtime for a whole kSAT set

# initAssign(F)

- RandomInit: build a complete assignment randomly
- BiasInit: assign true to a variable if the number of occurrences of its positive literal is larger than that of its negative literal.
- Bias-RandomInit: assign true to variable v<sub>i</sub> with probability posOccurences[i] posOccurences[i]+negOccurences[i].

# initAssign(F)

k	RandomInit	BiasInit	Bias-RandomInit
3	9221.9	9157.76	9078.27
	55	54	55
5	7143.9	4351.09	4582.54
	82	87	87
7	6238.51	5421.9	6310.7
	60	60	60

3SAT: RandomInit

5SAT and 7SAT: BiasInit

## pickVar(A.c)

- combine the random walk and stochastic selection
- pick greedy flips with zero breakcounts with a certain probability p.
- use the *SLS* with probability (1 p)

### Algorithmus 5 : Our pickVar

```
: current assignment A, unsatisfied clause c
input
```

parameter: probability p

**output**: a variable x in c to be flipped

- 1 *greedvVs*  $\leftarrow \emptyset$ ;
- 2 for all v in c do
- if (break(A,v)=0) then
- $greedyVs = greedyVs + \{v\}$
- 5 with probability p: x ← randomly selected variable v ∈ greedyVs;
- 6 with probability (1-p):  $x \leftarrow$  randomly selected variable v in c with probability  $\frac{\Gamma(A, \nu)}{\sum_{u \in \mathcal{L}} \Gamma(A, u)}$

## Variant 1: Walk

- statistic list S: how many times each variable is chosen for flipping
- The candidate with the small statistic value will be chosen.

 Getting the random literals using stochastic process consumes the most runtime.

# Variant 2: GreedyBreak

- permitted greedy literal: literal with zero breakcount and its statistic value is under a certain threshold t
- choose a permitted greedy literal randomly for flipping.
- if no permitted greedy literal exists, we pick a literal using SLS heuristic.
- 1st approach *Average*:  $t = \alpha \times \frac{numF}{numV}$
- 2nd approach *Random-Flip*:  $t = \alpha \times r$  with  $r \in [0, numF]$ .

# PickVar(A,c) with simulated annealing

### **Simulated Annealing**

- guide local search with a controlling parameter temperature.
- The temperature varies according to the score of the current situation.
- Higher temperature allows uphill moves with higher probability.

• Walk: 
$$p = \alpha \times \frac{s(randomV)}{s(greedyV) + s(randomV)}$$

- Average:  $t = \alpha \times \frac{numF}{numV}$
- Random-Flip:  $t = \alpha \times r$  with  $r \in [0, numF]$ .
- two variants of q(A):
  - $q_{global}(A) = unsatN(A)$
  - $q_{local}(A) = |\{v|v \in c \land break(v) = 0\}|$

### pickVar

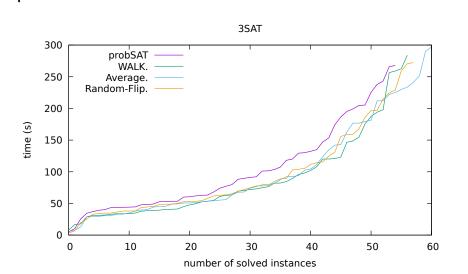

- probSAT:
  - implemented by the authors of the original paper
  - non-incremental approach to the 3SAT problems and incremental method for 5SAT and 7SAT
- yalSAT:
  - the third version of yalSAT submitted to the 2017 SAT competition
  - uses a variant of probSAT randomly in the restart of a searchround

k	probSAT	yalSAT	Walk	Average	Random-Flip
3	9221.9	17062.35	7430.12	6161.11	7308.01
	55	41	57	61	58
5	7143.9	5676.63	3330.61	2939.74	4003.06
	82	85	89	89	88
7	6238.51	10063.4	5409.67	3829.95	4903.61

pickVar

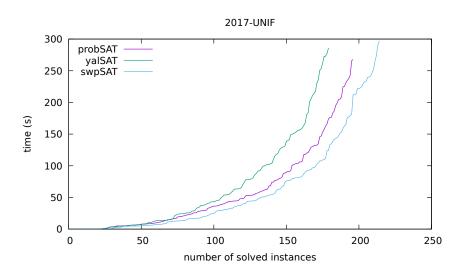

# Karkruher Institut für Technolog

swpSolver

## Outline

### Propositional Satisfiability Problem (SAT)

- **Notations**
- Local search in SAT problem

### Solving SAT by *swpSolver*

- Basic scheme
- Our improvements

### Our Parallel SAT-solver

- The pure portfolio approach
- Failures
- Initialization with a guide of formula partitioning

#### Conclusion

# The pure portfolio approach

- random generator affects the performance.
- the agents run the *swpSAT* with different random generation policies.

rand()	minstd_rand	mt19937

	89	94		
7	13406.26	2853.81	4.70	0.43
	66	83		

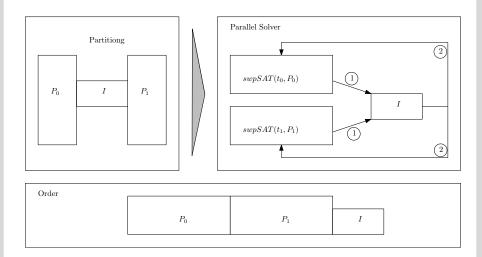

### benchmark COMBINE

- formula partitioning by a relatively balanced partitioning with small intersection
- combine two *UNIF* benchmark instances
- build the intersection based on a randomly chosen satisfying assignment
  - *BIG*: *COMBINE* problems with big intersection (numCl/numCl > 1%)
  - SMALL: COMBINE problems with big intersection (numCl < 1%)

## **Failures**

# Karkruher Institut für Technologie

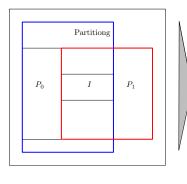

### 2nd Approach: Solver with formula partitioning

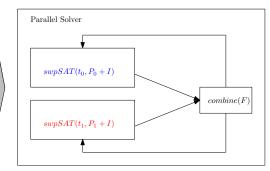

### **Failures**

### 3nd Approach: Solver with combination of sub-assignments

### Our Parallel GCP-solver

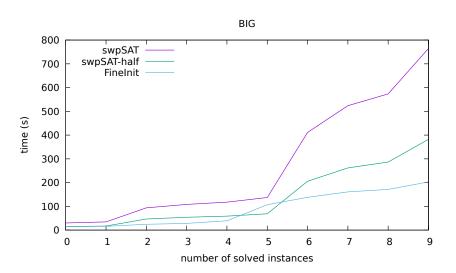

4th Approach: Initialization with formula partitioning (FineInit)

- The formula partitioning information is only used to get an initial solution.
- The statistic information shared among the agents encourages the further search to flip non-critical variables in clauses.
- The candidate with the smallest statistic value will be chosen in the next step.
- The agents use one common statistic matrix.

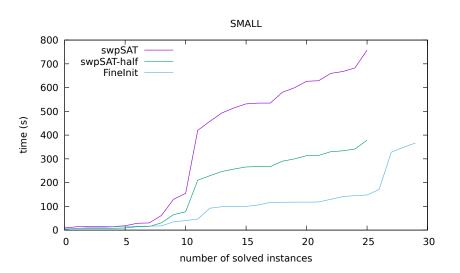

# Karkruher Institut für Technolog

benchmark COMBINE-BIG

# Kar kruher Institut für Technolog

benchmark COMBINE-SMALL

## Our parallel solver

- uses FineInit as initialization
- tries different search paths with pure portfolio approach

```
input: A CNF Formula F, number of Processors n_p1 A \leftarrow initAssign(F);2 foreach (Processor_t \text{ for } t \in \{1, ..., n_p\}) do3 A_t \leftarrow A;4 i \leftarrow t\%2;5 swpSAT(P_i);6 swpSAT(P_{1-i});7 while (!sat \land !Timeout) do8 A_t \leftarrow A;9 swpSAT(F);10 sat \leftarrow true;
```

# Karkruher Institut für Technolog

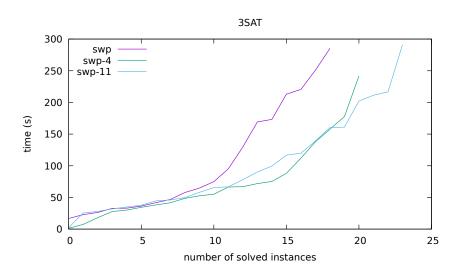

#### benchmark UNIF

- separate the vertices according their indices in two partition sets
- All vertices  $v_i$  with  $i < \frac{numV}{2}$  belong to  $P_0$ .
- The rest vertices belong to P<sub>1</sub>.

k	swp-4	S	E		S	Е
3	3350.36	1.49	0.37	2376.26	2.10	0.19
	21			24		
5	2535.86	1.23	0.31	1115.99	2.79	0.25
	30			33		
7	3874.51	1.28	0.32	1076.26	4.62	0.42
	22			27		

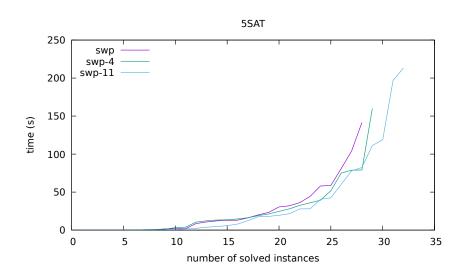

## 3SAT

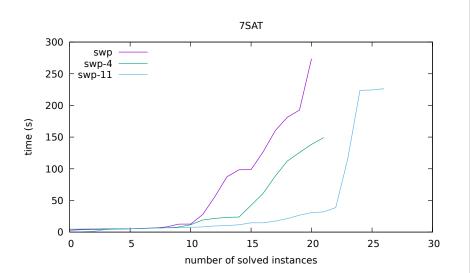

## **5SAT**

## 7SAT

## Conclusion

### Our improvement:

- a stochastic local search algorithm *swpSAT* with the incorporation of walkSAT and probSAT
- different local variants, which get better performance than the probSAT algorithm
- parallel *swpSAT* solver with formula partitioning
- the formula partitioning information can guide the local search

### **Further work**

- use different search strategies
- use different cooperation strategies
- use different random generation in local search

THANK YOU FOR YOUR ATTENTION ANY QUESTIONS?
